ABSTRACT

There is currently a paradigm shift from fossil based to biobased resources for the production of energy to attain the United Nations (UN) sustainability development goals related to good health, well-being, renewable and clean energy so as to overcome the catastrophic effects of climate change. Among various energy sources, the hydrogen energy stands out as the combustion of the fuel is free from CO₂ emissions. The hydrogen produced is indeed green if the energy used for the production of hydrogen from renewable sources like water electrolysis and the fermentation of carbohydrates, too comes from renewable sources like the solar energy, wind energy and the like rather than the electricity from the coal fired power plants. Efforts are ongoing in this direction and enormous advances have been made. Indeed, green hydrogen will be the energy source of the future provided, the currently set target by the United States (US) department of energy (DoE), namely, supplying hydrogen at the price of 1 USD/kg is realized by 2030. Fermentation process holds the key for green hydrogen production and supply at competitive prices. There are major obstacles towards the commercialization of green hydrogen as a substitute to the fossil fuels and the electric vehicles (EVs) that have been extensively used for transportation application. However, a transition to hydrogen economy can facilitate attaining the UN sustainable development goals, namely, the affordable and clean energy (goal 7) and climate action (goal 13). Thus the scope of the current status report is to highlight the latest advances made in green hydrogen production as well as distribution. We surmise that this report would serve as a standard protocol and user manual to the policy makers and investors dealing with the integration of green hydrogen with the transportation sector.

Keywords: Climate Change; Renewable Energy; Clean Energy; Green Hydrogen; Biohydrogen; Dark Fermentation; Photofermentation; Solar Fermentation.

INTRODUCTION

In the words of the world's richest man, Mr Elon Musk, the CEO of Tesla, "Hydrogen is the most dumb thing I could possibly imagine for energy storage." No offense. The cost of 1 kg of hydrogen is currently prohibitively high (10 USD) for

commercial scale utilization. However, the competing financial interests of the famous Mr Elon Musk could not be ruled out behind this statement, as hydrogen energy is the only competitor for the electric vehicles (EVs) promoted by Mr Elon Musk.

Energy crisis and environmental deterioration are the major challenges human societies are facing in the 21st century. The reasons behind the afore mentioned challenges are the indiscriminate use of fossil resources, rapid depletion of the extractable fossil based energy sources, including petrol, diesel and natural gas and the large amounts of greenhouse gases released into the atmosphere owing to the combustion of the fossil based energy sources. To alleviate the problems, it is surmised that carbon neutral fuels, especially, green hydrogen energy, should replace the currently used fossil based fuels both for industrial as well as transportation applications. Hydrogen (H_2) fuel is regarded as a green energy source as the net emission from the burning of H_2 is only water (H_2O), which is environmentally benign. Moreover, the gravimetric energy density of H_2 is the highest compared to any of the known materials (a lower heating value, LHV, of 120 MJ/kg and a higher heating value, HHV, of 143 MJ/kg). This means that the gravimetric energy density of hydrogen is nearly 2.6 - 3.1 times higher than the major fossil energy source, namely, gasoline (46 MJ/kg) [1].

Owing to the rapid advances made in the R and D on the three major aspects of green H_2 fuel namely, its production, storage and utilization, there is currently a paradigm shift from the use of fossil based resources to green hydrogen as fuel. Intensity of the R and D activity in the fertile area of green hydrogen can be comprehended from a web of science search with the keywords, namely, green and hydrogen, that yielded 45, 687 results (as on 13th February 2026). The steady growth in this field during the past decade (2016-2025) is viewed from the bar diagram shown in Figure 1, wherein the number of publications as a function of year were plotted. Moreover, in the year, 2025, itself, 7319 papers were published indicating the fertility of the energy source, namely, green hydrogen.

Figure 1: Rapid growth and intense R and D activity in the fertile area “Green hydrogen” during the past decade (2016-2025).

MATERIALS & METHODS

This status report used the literature from the scientific database, namely, Web of Science. As the quantum of research in the area of “Green hydrogen” is voluminous and exploding in nature, the scope of scanning the literature is limited only to the past five years (2021-2025) with the search keywords, namely, Green hydrogen. Moreover, only the topics, namely, Hydrogen production, storage, distribution and life cycle analysis, were considered and included in the report [1-42].

Goals for the Future Hydrogen Storage Materials

The goals set forth by the US department of energy (DoE) for the hydrogen storage materials with the corresponding gravimetric and volumetric energy density values were depicted pictorially in the work by Moller and co-workers. The ultimate goal of the US DoE pertaining to hydrogen energy storage is far far higher (gravimetric energy storage of 25 wt.% and volumetric energy storage of 180 kg H_2/m^3) which could be attained by possibly combining light elements with hydrogen in the solid state as in the case of NH_4BH_4 [1].

Possible Pathways for Reaching the set Goals towards Hydrogen Economy

This status report provides the possible pathways for reaching the far far higher targets. As voluminous data exists and many breakthroughs in the field have taken place, the authors have capsuled the content in the form of a table that systematically presents the developments that took place in the three major areas of green hydrogen, namely, Production of hydrogen from renewable sources, storage in sustainable and environmentally friendly solid state materials and applications leading to green environment and sustainability in energy [2-16]. Path breaking findings in the recent past are highlighted in the form of a table (Table 1).

S No	Highlights of the Advances	Reference
1	Green hydrogen – Production, storage and applications: State of the art, new challenges and opportunities Green hydrogen – Production methods Strategies for storage Applications State of the art technologies	17
2	Theory, modelling and simulation studies in Green hydrogen Artificial intelligence usage Modeling and simulations studies in catalysis and photocatalysis for green hydrogen production Theoretical studies for the design of catalysts, electrocatalysts and photoelectrocatalysts for green hydrogen production Role of Machine learning, artificial intelligence, theoretical studies in the storage and applications of green hydrogen	18
3	Large scale introduction of green hydrogen for net-zero greenhouse gas (GHG) emissions Net zero greenhouse gas emissions with green hydrogen – challenges ahead Electrolyser technologies - GHG emissions Integration of renewable electricity sources with hydrogen production Well-chosen production configuration and distribution methods for green hydrogen Strategies for GHG emission reduction in the production and distribution of green hydrogen Life cycle analysis of GHG emissions in green hydrogen production, storage and transport	2
4	Challenges in the scaling up of green hydrogen and achieving climate targets Green hydrogen for attaining climate targets Green hydrogen and derived fuels as substitute to fossil fuels; Green hydrogen critical for climate neutrality Short term scarcity and long term uncertainties in green hydrogen; Energy policies and incentives for boosting hydrogen production and availability	19

5	Orange hydrogen as a new green hydrogen Orange hydrogen as a substitute to black and grey hydrogens Achieving Paris agreement climate targets with green hydrogen Steam reforming of coal and natural gas for hydrogen production Coupling of electrolysis of water with renewable energy – green hydrogen Expensive and energy intensive nature of green hydrogen Rock based hydrogen production and carbon sequestration – white and orange hydrogen	5
6	Electroreforming of biomass for green hydrogen production Coupling of organic electrooxidation with hydrogen production; Coupling electroreforming of biomass with green hydrogen production Electrooxidation of chitin acetate Solar energy driven electrooxidation of chitin and chitin derivatives and shrimp shells Scaling up studies on the electroreforming of biomass for green hydrogen	7

New insights based on critical analysis of the latest innovation highlighted in Table 1 in the field of green hydrogen were

shown in Scheme 1 with emphasis on the market trends and requirements.

Scheme 1: New insight on the innovation and market trends in green hydrogen

DISCUSSION

Integration of solar energy with the biohydrogen production

Gedenken's group pioneered in the use of solar energy for the accelerated production of bioethanol [43]. Glucose feedstock of concentration as high as 40 wt. % was converted to 19.5 wt. % bioethanol. Classical fermentation problems like the product ethanol poisoning of yeast could be surmounted as the formed bioethanol is separated from the fermentation broth soon after its formation by the unique evaporation-condensation process operating in the specially designed solar reactor. The solar reactor used for the fermentation of glucose and other biomass namely, cellulose, and marine macroalgae *Ulva rigida* was made up of Aluminum metal. Herein we propose the fabrication of the solar reactor of similar design using carbon fiber reinforced composite (CFRC) material. Use of such CFRC for solar reactor fabrication has several advantages including durability, light weight, enhanced solar energy harvesting, and acceleration of kinetics of fermentation of glucose to biohydrogen [44-46].

Figure 2: Solar reactor for the accelerated fermentation of Carbohydrates to hydrogen proposed to be fabricated using carbon fiber reinforced composite (CFRC)

CONCLUSION

To facilitate easy and ready contact between the investors and the inventors, the contacts of 34 pioneers in the field of green hydrogen were provided in the form of references and such a style of presentation is the first of its kind in scientific literature and is expected to be a trend setter to meet the demand. New insights on the design of special solar reactor made up of the carbon fiber reinforced composites for integrating the fermentation of carbohydrates with the solar energy for the accelerated production of green biohydrogen were provided. Integrating solar energy with photo-fermentation in solar reactors accelerates the conversion of biomass to green hydrogen. Like-wise, the integration of electrolyzers with renewable energy sources leads to the sustainable production of green hydrogen. Doping of light elements (B, N, C) in carbon materials as well as the appropriate choice of compounds of light elements with high hydrogen content as in the case of NH_4BH_4 -carbon nanodot composites leads to gravimetric hydrogen storage as high as 25 wt. %. With new insight on the green hydrogen production, storage, distribution, life-cycle analysis as well as the techno-economic analysis, this status report on green hydrogen is envisioned to serve as a user manual for the large body of the scientific community.

AUTHOR CONTRIBUTION

ST is the ideator and supervisor; MSS reviewed and edited the paper and provided new insights; INP wrote the original manuscript.

ACKNOWLEDGEMENTS

Thankfulness is due to Professor Deepak Nallaswamy Veeraiyan for providing the opportunity to INP to work at SIMATS. Gratefulness is due to Mr Anandamurugan, Librarian, and the staff of the central library for access to the knowledge resources. Indebtedness is due to Mrs Saradhambal V, Superintendent, for the facilities at the Nalanda Light Reading Hall, Central library, IIT Madras. Thanks are due to Professor Rajakumar Balla, Chairman, Central Library, IIT Madras for the facilities. Indebtedness is due to Professor S Elangovan, Head of the department, ENT, for the motivation and support.

CONFLICT OF INTEREST

The authors declare no conflicts of interest.
